Metal-free trifluoromethylthiolation of arenediazonium salts

Giulia Bertoli, Benjamin Exner, Mathies V. Evers, Kristina Tschulik and Lukas J. Gooßen (giulia.bertoli@rub.de Ruhr Universität Bochum

Abstract

Fluorine-containing molecules are central functionalities imparting unique chemical and physical properties, such as improved solubility, bioavailability and adhesive properties compared to the non-fluorinated counterparts.^[1] New and efficient methods for the introduction of fluorine moieties are constantly sought after. Herein, a metal-free entry to the substrate class of trifluoromethyl thioethers is reported starting from widely available arenediazonium salts and commercial Me₄N⁺SCF₃⁻ under mild conditions.

Importance of Trifluoromethylthio Groups

About 25% of all pharmaceuticals and 30-40% of agrochemicals on the market fluorine. Therefore, contain the introduction of fluorinated groups has become of great interest in drugdiscovery. In particular SCF₃ groups induce even higher lipophilicity and membrane permeability compared to their CF₃ analogues.^[2]

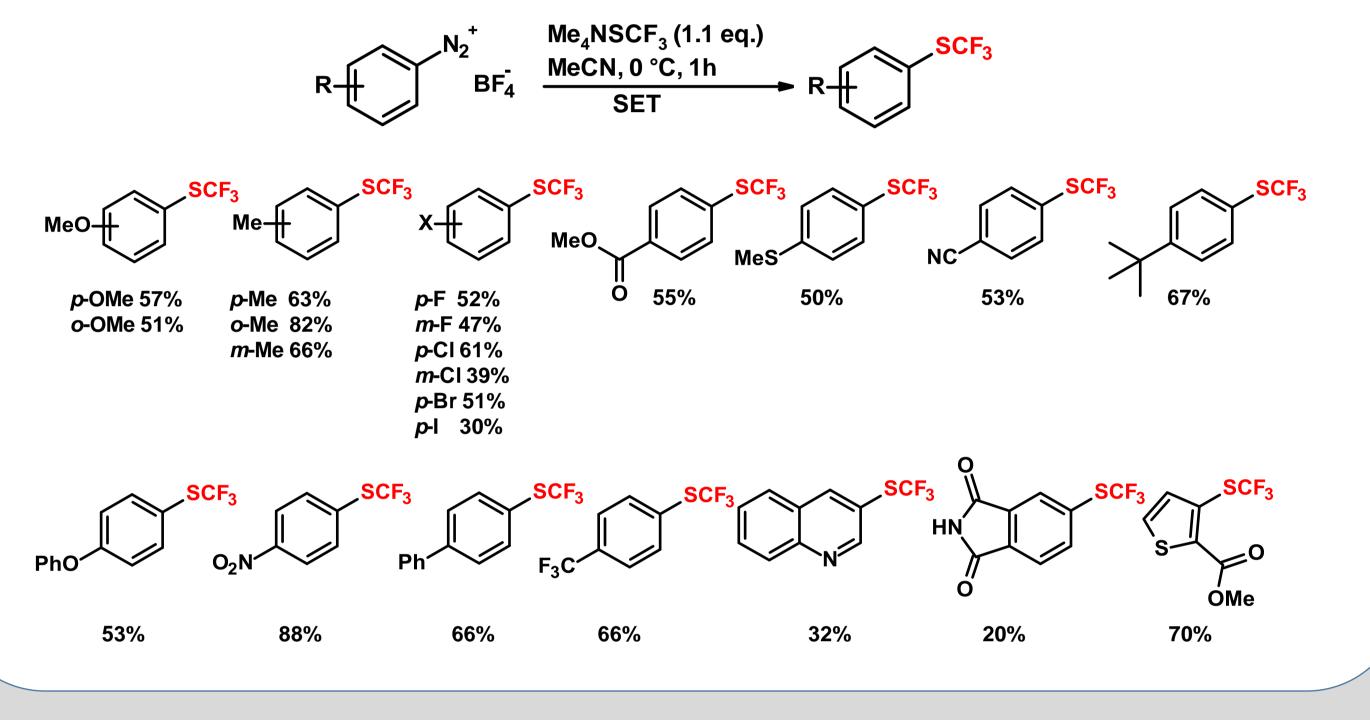

Traditional strategies for the preparation of trifluoromethylthiolated compounds are based on waste-intensive, multistep syntheses involving halogen-fluorine exchange reactions.^[3]

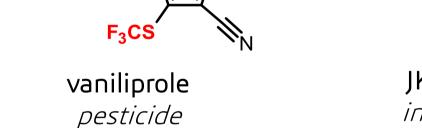

Metal-free Trifluoromethylthiolation

Still, for pharmaceutical and agrochemical applications, it would be best if heavy metals could be left out altogether. Herein, we present a metal-free approach for the synthesis of valuable trifluoromethylthioethers.^[5]

Study of the thermodynamics

SCF₃

Sandmeyer-type Trifluoromethylthiolation

In the last years, several methods were developed to introduce the SCF_3 group as a whole, but a particularly straightforward approach is the copper-catalyzed trifluoromethylthiolation Sandmeyer-type of arenediazonium salts using Me₄NSCF₃ as the SCF₃ source.^[4]

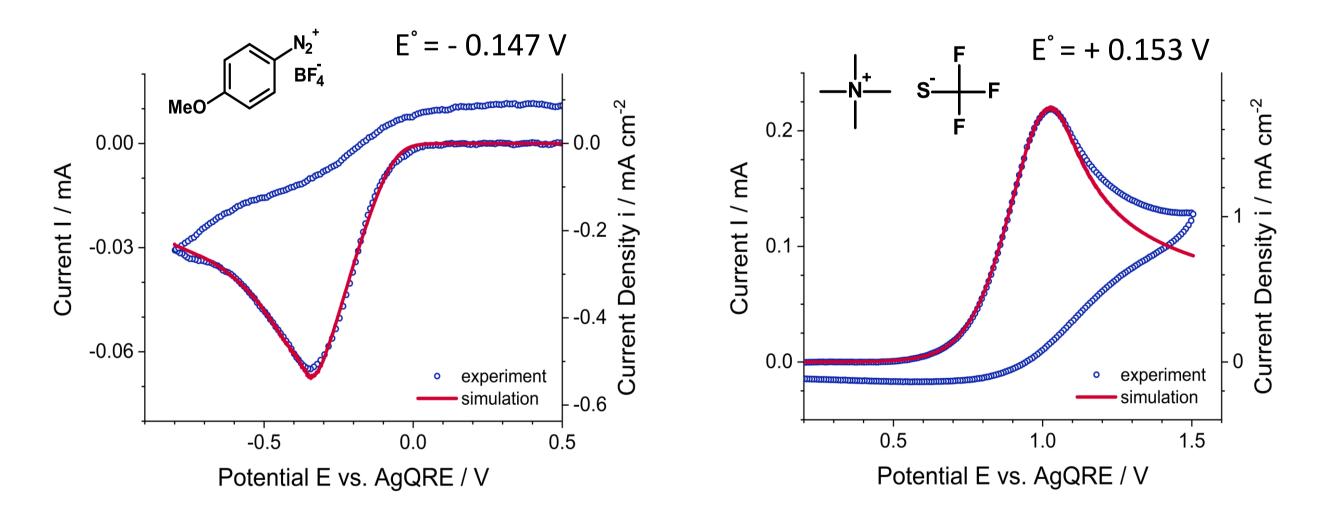

This approach is remarkable in that it is one of the few processes in which only substoichiometric amounts of copper are required to achieve high yields.

Proposed mechanism

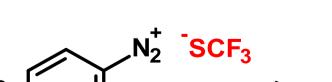

The reaction follows a classical Sandmeyer-type single-electron-transfer (SET) pathway involving aryl radicals.

To highlight the mechanism we addressed the thermodynamics of this reaction by cyclic voltammetry studies. Cyclovoltammetric curves of 4methoxybenzenediazonium tetrafluoroborate and Me₄NSCF₃ show a SET process in both cases. Using these experimental data, the activation energy was calculated ($\Delta G = - zFE = 28.9 \text{ kJ/mol}$) showing that this barrier can be easily crossed in absence of metals or radical initiators.

Proposed mechanism

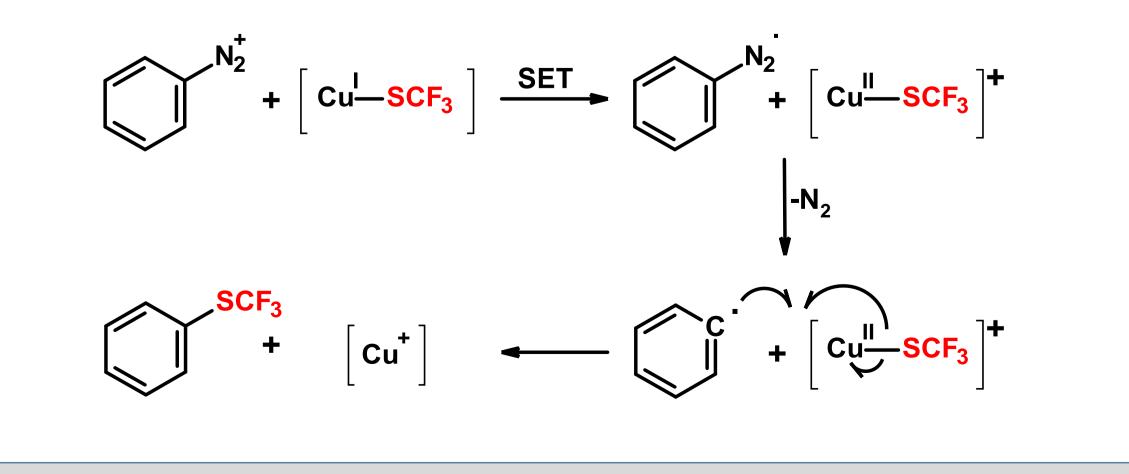

Based on these findings, we proposed a radical mechanism that consists of reduction of the diazonium species by the SCF_3^- anion, followed by dediazotization and subsequent recombination of two radical species.

$\underbrace{\mathsf{SET}}_{\mathsf{R}} \mathsf{R} \xleftarrow{} \mathsf{SCF}_3 \xrightarrow{} \mathsf{R} \xleftarrow{} \mathsf{R} \xleftarrow{} \mathsf{R} \xleftarrow{} \mathsf{SCF}_3 \xrightarrow{} \mathsf{R} \xleftarrow{} \mathsf{R} (\mathsf{R} \mathbin{R} \xleftarrow{} \mathsf{R} \xleftarrow{} \mathsf{R} (\mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} \mathsf{R} (\mathsf{R} \mathsf{R} (\mathsf{R}$ R+

Conclusion

Overall, this study demonstrates that it is possible to perform trifluoromethylthiolations of arene electrophiles in the absence of heavy metal mediators with mild conditions and short reaction times.
